Subject: Waste Management of Wisconsin, Inc. - Orchard Ridge Recycling and Disposal Facility Proposed Eastern Expansion, Southern Unit
Plan of Operation - Addendum 2
Village of Menomonee Falls, Waukesha County, Wisconsin
License No. 4491
Dear Ms. Bekta:
On behalf of Waste Management of Wisconsin, Inc. (WMWI), this letter to respond to the Wisconsin Department of Natural Resources (WDNR)'s request to revise the pipe strength calculations to utilize a higher unit weight of waste.

Per a discussion between WMWI and the WDNR, it was requested that the pipe strength calculations submitted in the Orchard Ridge Recycling and Disposal Facility, Proposed Eastern Expansion, Southern Unit (Southern Unit) Plan of Operation, dated February 2022 (Feb 2022 POO) be revised using a conservative and theoretical unit of weight of wet waste of 119 pounds per cubic foot (pcf) that was previously presented in the 2018 East Expansion Plan of Operation's stability analysis.

Per WDNR's request, the shallow and deep loading conditions of the pipe strength calculations were revised to account for the requested unit weight of waste. These updated calculations are provided in Attachment 2. WMWI and TRC trust that we have provided the information requested by the Department. Per the Department's request, only electronic versions of this Addendum have been provided.

WMWI is requesting that the WDNR review and provide a complete Plan of Operation determination for the proposed Southern Unit. Please feel free to contact Tyler Field, at 262-443-2240 or Michael Amstadt at 608-358-2669 with any questions regarding this document.

Sincerely,

## TRC

Michael Amstadt, P.E.
Principal Project Manager

## PIPE STRENGTH CALCULATIONS

## Purpose:

Pipe strength calculations demonstrate that the proposed piping for the Orchard Ridge Recycling and Disposal Facility (Orchard Ridge RDF) Eastern Expansion, Southern Unit (Southern Unit) will withstand the loading conditions during construction and long-term performance.

## Methodology:

## Loading:

There are two sources of loading on the leachate collection system piping: live (vehicular) loading and soil loading in the vertical prism above the pipe. Soil loading is determined by summing the product of the unit weight and corresponding thickness of each layer. For wheeled equipment, the Boussinesq equation gives the resulting pressure on the pipe from a concentrated load anywhere above the pipe. Area loading, e.g. tracked equipment, is determined using the Area Loading equation. Each equation considers the depth of fill above the pipe and surface loading to determine the resulting load on the pipe. Live loads from tracked (area load) and wheeled (point load) equipment are compared to determine worst case loading (PPI, 2009).

## Pipe Strength:

Pipe perforations cause a reduction in pipe strength. To account for this reduction, loading values from soil and equipment are increased using the Loading Adjustment Equation for Perforations (Duffy, 2006). Adjusted loading values are incorporated into calculations to assess deflection, wall compression, buckling, and, for shallow fill, "membrane" bending of the pipe crown:

- Deflection due to the load on the pipe is calculated using the Modified lowa equation for depths less than 50 feet. The resulting value is compared to recommended values (PPI, 2009).
- Compressive stress in the wall of the pipe is determined using the Wall Compression equation. This equation uses the Standard Dimension Ratio (SDR) to evaluate the effects from loading on the pipe. The resulting value is compared to allowable values for the pipe material (PPI, 2009).
- Allowable pressure to prevent buckling is calculated using Unconstrained Pipe Wall Buckling equation for shallow fills less than 4 feet and Constrained Pipe Wall Buckling equation for fills greater than 4 feet. Resulting values are compared to pressure from live loads and soil loads.
- Allowable loading to prevent the "membrane" bending effect in shallow fills of the pipe crown is determined using the Watkins equation. Resulting values are compared to pressure from live loads and soil loads.

For pipes buried under fills greater than 50 feet, live loads are neglected, and Watkins' method is used to calculate ring compressive force and pipe deflection from the weight of the soil column. Ring compressive force is compared to the long-term compressive strength demonstrates the pipes' abilities to withstand crushing. Watkins' method states that the deflection of the pipe is limited by the deflection of the sideslope soil surrounding the pipe and calculating the potential deflection of the sideslope soils determines the maximum possible deflection of the pipe. Percent deflection due to the soil column is compared to recommended values for cleanout operational equipment (Harrison and Watkins, 1996).

Pipe strength properties (i.e. pipe stiffness, wall thickness, and pipe flexural modulus) and the support provided by the soil (i.e. soil modulus) are used to determine the maximum allowable confined buckling pressure and compared to the maximum dead load due to the column of waste and cover soil over the pipe.

## Assumptions:

## Loading Conditions

Three loading conditions were analyzed for both the 6 -inch leachate collection pipe and 18-inch leachate sideslope riser pipe. These loading conditions are summarized below.

- Short-term loading during the construction of the select aggregate drainage layer: Select aggregate fill depth over the pipes is minimized ( 2.5 -feet over leachate collection pipes and 3 feet over the sideslope riser pipe) to maximize the live load from equipment. For the short-term strength analysis, the maximum live load on the pipe during construction (minimum fill cover depth) uses the following typical equipment specifications (Caterpillar, 2010):
- Cat D11 Dozer
- Cat 745 C Dump Truck

Note that equipment loads used in this calculation were selected to represent extreme loading conditions on the proposed pipe to confirm the pipe strength. During construction, equipment used during construction will be restricted to meet the requirements of $s$. NR 504.06(3)(h).

- Shallow long-term loading of the pipes under select aggregate fill (depths listed above) and waste fill ( 2 feet) was also analyzed. Under this condition, cover is minimized and live-loading is maximized.
- Deep long-term loading:
- For the leachate collection pipe:
- 2.5 feet of select aggregate fill,
- 220.7 feet of waste fill,

| PROJECT/PROPOSAL NAME | PREPARED |  | CHECKED |  | PROJECT/PROPOSAL NO. |
| :--- | :--- | :--- | :--- | :--- | :---: |
| Waste Management of Wisconsin, Inc. | By: | Date: | By: | Date: |  |
| Orchard Ridge RDF Eastern | J. Bell | $8 / 12 / 2021$ | A. Rowley | $8 / 13 / 2021$ |  |
| Expansion, Southern Unit | A. Rowley | $11 / 10 / 2021$ | B. Kahnk | $11 / 10 / 2021$ |  |
| Plan of Operation | B. Kahnk | $9 / 28 / 2022$ | M. Amstadt | $9 / 29 / 2022$ |  |

- 2 feet of select compacted clay, and
- 2.5 feet of general fill (rooting zone).

Depths are maximized under this condition. The maximum waste thickness proposed is located within the vertical overlay area in the East Expansion limits of waste. The maximum waste thickness within the lateral expansion area is 198 feet ; therefore, the critical condition is located within the vertical overlay area.

- For the sideslope riser pipe:
- 3 feet of select aggregate fill,
- 56.9 feet of waste fill,
- 2 feet of select compacted clay, and
- 2.5 feet of general fill (rooting zone).

Depths are maximized under this condition. The maximum waste thickness proposed is located within the lateral expansion area outside the limits of waste for the East Expansion. The maximum waste thickness within the East Expansion vertical is 51.90 feet; therefore, the critical condition is located within the lateral expansion area.

- For the long-term strength analysis, live loads are considered insignificant at high fill depths. Therefore, the maximum static load on the pipe following closure uses the following soil layer unit weights (based on laboratory analysis and TRC experience):
- Rooting zone and topsoil $=115$ pounds per cubic foot (pcf)
- Select Compacted Clay (Soil Barrier Layer) = 130 pcf
- Waste Fill = 119 pcf
- Select Aggregate Fill = 125 pcf

It should be noted that the waste fill unit weight is considered highly conservative. Proposed final waste grades and final cover configuration were used to calculate the worst-case dead load conditions after closure.

## Piping Applications

- For the Southern Unit, pipe strength was considered for the following applications:
- 6-inch SDR 11 HDPE perforated leachate collection pipe
- 18-inch SDR 11 HDPE perforated sideslope riser pipe

| Plan of Operation | B. Kahnk | $9 / 28 / 2022$ | M. Amstadt | $9 / 29 / 2022$ |  |

- Open-channel flow conditions without pressure (i.e., pipes do not run full) are assumed for all pipes.
- Flexible plastic pipe can withstand varying levels of deflection based on material and thickness; however, a range of $5-7.5 \%$ has become the standard allowable deflection to prevent access issues during cleaning or servicing (LamsonVylon, 2010).
- Longitudinal strain of the piping is not applicable at the Southern Unit. Straining is caused by inconsistent support by the pipe bedding (Harrison and Watkins, 1996); however, under continuous bedding and construction on firm foundation, it is disregarded.
- Tangential strain of the piping is not applicable at the Southern Unit. It is calculated on the basis of deflection, pipe Standard Deflection Ratio (SDR), and pipe outside diameter. The allowable tangential strain of the pipes will not be exceeded if the allowable deflection is not exceeded (Harrison and Watkins, 1996).

## Pipe Compressive Strength and Thermal Compatibility

With atmospheric temperatures during summer construction potentially reaching $100^{\circ} \mathrm{F}$, and elevated temperature due to biological activity within the landfill, a temperature de-rating factor of 0.78 was applied to the standard compressive strength for a high-density polyethylene (HDPE) pipe to obtain a compressive strength of [780 psi (1,000 psi $\times 0.78)$ ] for the short-term and long-term analyses (PPI, 2009).

## Pipe Perforations

When the perforation open space of the $1 / 2$-inch diameter holes (spaced at 180 degree intervals around the pipe laterally and every 6 inches for the 6 -inch SDR 11 HDPE perforated leachate collection pipe or spaced at 90 degree intervals around the pipe laterally and every 6 inches for the 18 -inch SDR 11 HDPE perforated sideslope riser pipe) was compared to the surface area of the pipes, the perforation open area was deemed to be minimal. The effect of perforations is negligible in comparison to the factors of safety that was achieved for deflection and ring compression calculations. See attachments for further calculations.

## Pipe Bedding

The bedding constrained modulus (one-dimensional modulus) used to determine the deflection of the soil in Watkins' method is defined by soil type, compaction, and stress level applied to the soil. For the proposed pipes embedded in select aggregate fill, the stress level at each piping application assumes the bedding material is placed at a minimum of 90 percent of the material's modified proctor value ( 95 percent standard proctor value). The result is a constrained soil modulus of $6,500 \mathrm{psi}$ (PPI, 2009). For soil reaction modulus, values between 1500 psi and 2500 psi were used for the shallow burial scenarios, dependent on the burial depth condition.

## Results:

## Construction Loading

The results of Boussinesq's formula show that compressive strength of the HDPE pipe will not be exceeded during construction conditions with a minimum of 18 inches of cover material over the pipe before loading is applied. For each piping application, the calculated pipe loading is well below the allowable compressive strength of 1000 psi for HDPE at $73^{\circ} \mathrm{F}$.

## Post Closure Long Term Loading

The results of Watkins' Method show that the ring compression force does not exceed the maximum allowable design long-term compressive strength of 780 psi for the proposed pipes. Additionally, based on the anticipated deflection of the sideslope soil, the allowable deflection of $5-7.5 \%$ was also not exceeded. Lastly, the maximum design load for each piping application was less than each pipe's respective calculated allowable buckling pressure. Based on these results, the proposed pipe design is adequate and appropriate for the anticipated construction, operation, and closure loading conditions. See tables below for the result summaries of the different conditions.

Live-Loading Inputs:
Soil Inputs:

| SOIL LAYER | SOIL TYPE | UNIT WEIGHT (pcf) | SOIL LAYER THICKNESS (ft) | $\begin{aligned} & \text { SOIL LAYER } \\ & \text { LOAD } \\ & \text { (psi) } \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: |
| 1 | Select Aggregate Fill | 125 | 2.5 | 2.17 |
| 2 | Waste Fill | 119 | 2.0 | 1.65 |

Wheeled Vehicle Inputs:

| VEHICLE NO. | VEHICLE DESCRIPTION | NO. OF WHEELS | WEIGHT DISTRIBUTION | OPERATING WEIGHT (lbs) | WEIGHT PER WHEEL (lbs) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | CAT 745 C Dump Truck | 6 | 0.34/0.33/0.33 | 164024 | 27,884 |
| 2 | Ford F-150 Truck | 4 | 0.25 | 5014 | 1,254 |

$$
\text { => For wheeled vehicles the CAT } 745 \text { C Dump Truck load is the largest, }
$$

thus use 27884.08 lb . to determine PL
Tracked Vehicle Inputs:

| VEHICLE NO. | VEHICLE TYPE | OPERATING WEIGHT PER <br> TRACK <br> (lbs) | TRACK WIDTH <br> (ft) | TRACK LENGTH <br> (ft) | WEIGHT PER TRACK <br> (lbs) | GROUND CONTACT <br> AREA PER TRACK <br> (in ${ }^{2}$ ) | DISTRIBUTED LOAD PER TRACK (psi) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 3 | CAT D11 Dozer | 114924 | 2.33 | 14.6 | 57,462 | 4,900 | 12 |
|  |  |  |  |  |  |  |  |

=> For tracked vehicles the 12 psi load is the largest,
thus use 12 psi to determine PLS

## Live-Loading Calculation:

Equations (PPI, 2009):
Boussinesq Equation for Point (Wheeled) Loading Eq 3-4 (PPI, 2009):

$$
P_{L}=\frac{3 I_{z} P H^{3}}{2 \pi r^{5}}
$$

$$
r=\left(X^{2}+H^{2}\right)^{1 / 2}
$$

| PARAMETER | DESCRIPTION | VALUE | UNITS | ASSUMPTION/REFERENCE |
| :---: | :---: | :---: | :---: | :---: |
| Iz | Road Type Impact Factor | 2 | unitless | For dirt roads (PPI, 2009) |
| P | Concentrated Surface Load | 27884.08 | lbs | CAT 745 C Dump Truck has the largest load |
| H | Depth of Soil Cover | 54 | in | User input "Soil Inputs" table |
| X | Horizontal Distance of Wheel from Pipe | 0 | in | $\mathrm{r}=\mathrm{H}$ for one wheel directly above the pipe |
| r | Radial Distance of Load from Pipe | 54 | in | Wheel is directly above the pipe |
| PL | Vertical Pressure Acting on the Pipe | $\mathbf{9 . 1 3}$ | psi | Calculated Value |

Area (Track) Loading Equation Eq 3-8 (PPI, 2009):

## Pipe Strength Reduction From Perforations

Loading Adjustment Equation for Perforations (Inverse of Pipe Strength Reduction) (Duffy, 2006):

$$
P_{L V}=\frac{12 *\left(P_{L} \text { or } P_{L S}\right)}{12-D * N} \quad P_{E}=\frac{12 * \sum[(\text { Soil Layer Depth }) *(\text { Soil Layer Unit Weigh }}{12-D * N}
$$

| PARAMETER | DESCRIPTION | VALUE | UNITS | ASSUMPTION/REFERENCE |
| :---: | :---: | :---: | :---: | :---: |
| D | Perforation Diameter | 0.5 | in | $1 / 2^{\prime \prime}$ perforation |

Boussinesq's Formula

## Boussinesq Equation

The Boussinesq Equation gives the pressure at any point in a soil mass under a concentrated surface load. The Boussinesq Equation may be used to find the pressure transmitted from a wheel load to a point that is not along the line of action of the load. Pavement effects are neglected.
(3-4)

$$
P_{L}=\frac{3{ }_{f}}{2 \pi r^{5}}
$$

## WHERE

$\mathrm{P}_{\mathrm{L}}=$ vertical soil pressure due to live load $\mathrm{lb} / \mathrm{ft}^{2}$
= wheel load, ib
= vertical depth to pipe crown, ft
$f=$ impact factor
$r=$ distance from the point of load application to pipe crown, ft
(3-5)

$$
r=\sqrt{2^{2}+2^{2}}
$$

Figure 3-4 Illustration of Boussinesq Point Loading

## Example Using Boussinesq Point Loading Technique

Determine the vertical soil pressure applied to a $12^{\prime \prime}$ pipe located 4 ft deep under a dirt road when two vehicles traveling over the pipe and in opposite lanes pass each other. Assume center lines of wheel loads are at a distance of 4 feet. Assume a wheel load of $16,000 \mathrm{lb}$.

## Watkins Method

Compare this with the constrained buckling pressure. Since $P_{w C}$ exceeds $P_{E}, D R 26$ has satisfactory resistance to constrained pipe buckling.

## Installation Category \#2: Shallow Cover Vehicular Loading

The Standard Installation methodology assumes that the pipe behaves primarily as a "membrane" structure, that is, the pipe is almost perfectly flexible with little ability to resist bending. At shallow cover depths, especially those less than one pipe diameter, membrane action may not fully develop, and surcharge or live loads place a bending load on the pipe crown. In this case the pipe's flexural stiffness carries part of the load and prevents the pipe crown from dimpling inward under the load. Equation 3-19, published by Watkins ${ }^{(14)}$ gives the soil pressure that can be supported at the pipe crown by the combination of the pipe's flexural stiffness (bending resistance) and the soil's internal resistance against heaving upward. In addition to checking Watkins' formula, the designer should check deflection using Equations 3-10 or 3-11, pipe wall compressive stress using Equations 3-13 or 3-14, and pipe wall buckling using Equations 3-15 or 3-16.

Watkins' equation is recommended only where the depth of cover is greater than one-half of the pipe diameter and the pipe is installed at least 18 inches below the road surface. In other words, it is recommended that the pipe regardless of diameter always be at least $18^{\prime \prime}$ beneath the road surface where there are live loads present; more may be required depending on the properties of the pipe and installation. In some cases, lesser cover depths may be sufficient where there is a reinforced concrete cap or a reinforced concrete pavement slab over the pipe. Equation 3-19 may be used for both DR pipe and profile pipe. See definition of " $A$ " below.
(3-19)

$$
P_{W A T}=\frac{12 \mathrm{w}(K H)^{2}}{N_{S} D_{o}}+\frac{7387(I)}{N_{S} D_{o}{ }^{2} c}\left(S_{M A T}-\frac{\mathrm{w} D_{o} H}{288 A}\right)
$$

## WHERE

$P_{\text {WAT }}=$ allowable live load pressure at pipe crown for pipes with one diameter or less of cover, psf
$\mathrm{W}=$ unit weight of soil, $\mathrm{lb} / \mathrm{ft}^{3}$
$\mathrm{D}_{\mathrm{O}}=$ pipe outside diameter, in
$\mathrm{H}=$ depth of cover, ft
I = pipe wall moment of inertia ( $\mathbf{t}^{3} / 12$ for DR pipe), in ${ }^{4} /$ in
A = profile wall average cross-sectional area, in ${ }^{2} / \mathrm{in}$, for profile pipe or wall thickness (in) for DR pipe (obtain the profile from the manufacturer of the profile pipe.)
$\mathrm{C}=$ outer fiber to wall centroid, in
$\mathrm{C}=\mathrm{H}_{\mathrm{P}}-\mathrm{z}$ for profile pipe and $\mathrm{c}=0.5 \mathrm{t}$ for DR pipe, in
$H_{P}=$ profile wall height, in
Z= pipe wall centroid, in
$\mathrm{S}_{\text {MAT }}=$ material yield strength, $\mathrm{Ib} / \mathrm{in}^{2}$, Use $\mathbf{3 0 0 0}$ PSI for PE3408

## $N_{S}=$ safety factor

$K=$ passive earth pressure coefficient
${ }^{(3-20)} \mathrm{K}=\frac{1+\operatorname{SIN}(\phi)}{1-\operatorname{SIN}(\phi)}$
$\phi=$ angle of internal friction, deg

Equation 3-19 is for a point load applied to the pipe crown. Wheel loads should be determined using a point load method such as given by Equations 3-2 (Timoshenko) or 3-4 (Boussinesq).

When a pipe is installed with shallow cover below an unpaved surface, rutting can occur which will not only reduce cover depth, but also increase the impact factor.

## Shallow Cover Example

Determine the safety factor against flexural failure of the pipe accompanied by soil heave, for a $36^{\prime \prime}$ RSC 100 F894 profile pipe 3.0 feet beneath an H20 wheel load. Assume an asphalt surface with granular embedment.

SOLUTION: The live load pressure acting at the crown of the pipe can be found using Equation 3-4, the Boussinesq point load equation. At 3.0 feet of cover the highest live load pressure occurs directly under a single wheel and equals:

$$
P_{L}=\frac{(3)(2.0)(6000)(3.0)^{3}}{2 \pi(3.0)^{5}}=1697 \mathrm{psf}
$$

## WHERE

$\mathrm{I}_{\mathrm{f}}=2.0$
$\mathrm{W}=16,000 \mathrm{lbs}$
$\mathrm{H}=3.0 \mathrm{ft}$
$\mathrm{w}=120 \mathrm{pcf}$

The live load pressure is to be compared with the value in Equation 3-19. To solve Equation 3-19, the following parameters are required:

```
I = 0.171 in4/in
A=0.470 in2/in
HP=2.02 in (Profile Wall Height)
DO}=\mp@subsup{D}{1}{}+2*h=36.00+2*2.02=40.04 i
Z=0.58 in
C=h-z=1.44 in
S=3000 psi
\phi = 30 deg.
```

## Buckling

raised to a power. Therefore the lower the DR, the higher the resistance. Buried pipe has an added resistance due to support (or constraint) from the surrounding soil.

Non-pressurized pipes or gravity flow pipes are most likely to have a net compressive stress in the pipe wall and, therefore, the allowable buckling pressure should be calculated and compared to the total (soil and ground water) pressure. For most pressure pipe applications, the fluid pressure in the pipe exceeds the external pressure, and the net stress in the pipe wall is tensile. Buckling needs only be considered for that time the pipe is not under pressure, such as during and immediately after construction and during system shut-downs and, in cases in which a surge pressure event can produce a temporary negative internal pressure. Under these circumstances the pipe will react much stiffer to buckling as its modulus is higher under short term loading. When designing, select a modulus appropriate for the duration of the negative external pressure. For pipe that are subjected to negative pressure due to surge, consideration should be given to selecting a DR that gives the pipe sufficient unconstrained collapse strength to resist the full applied negative pressure without support for the soil. This is to insure against construction affects that result in the embedment material not developing its full design strength.

This chapter gives two equations for calculating buckling. The modified Luscher Equation is for buried pipes that are beneath the ground water level, subject to vacuum pressure, or under live load with a shallow cover. These forces act to increase even the slightest eccentricity in the pipe wall by following deformation inward. While soil pressure alone can create instability, soil is less likely to follow deformation inward, particularly if it is granular. So, dry ground buckling is only considered for deep applications and is given by the Moore-Selig Equation found in the section, "Buckling of Pipes in Deep, Dry Fills".

## Luscher Equation for Constrained Buckling Below Ground Water Level

For pipes below the ground water level, operating under a full or partial vacuum, or subject to live load, Luscher's equation may be used to determine the allowable constrained buckling pressure. Equation 3-15 and 3-16 are for DR and profile pipe respectively.
(3-15) $P_{W C}=\frac{5.65}{N} \sqrt{R B^{\prime} E^{\prime} \frac{E}{12(D R-1)^{3}}}$
(3-16) $P_{W C}=\frac{5.65}{N} \sqrt{R B^{\prime} E^{\prime} \frac{E l}{D_{M}^{3}}}$

## WHERE

$\mathrm{P}_{\mathrm{WC}}=$ allowable constrained buckling pressure, $\mathrm{lb} / \mathrm{in}^{2}$
$N=$ safety factor

$$
{ }^{(3-17)} \mathrm{R}=.33-\mathrm{w}
$$

## WHERE

$R=$ buoyancy reduction factor

$$
\mathrm{w}=\text { height of ground water above pipe, } \mathrm{ft}
$$

$=$ depth of cover, ft
(3-18)
$B^{\prime}=\square .65$

```
WHERE
    = natural log base number, 2.71828

DM= Mean diameter ( }\mp@subsup{D}{1}{}+2z\mathrm{ or D D - t), in
```

Although buckling occurs rapidly, long-term external pressure can gradually deform the pipe to the point of instability. This behavior is considered viscoelastic and can be accounted for in Equations 3-15 and 3-16 by using the apparent modulus of elasticity value for the appropriate time and temperature of the loading. For instance, a vacuum event is resisted by the short-term value of the modulus whereas continuous ground water pressure would be resisted by the 50 year value. For modulus values see Appendix, Chapter 3.
For pipes buried with less than 4 ft or a full diameter of cover, Equations 3-15 and 3-16 may have limited applicability. In this case the designer may want to use Equations 3-39 and 3-40.

The designer should apply a safety factor commensurate with the application. A safety factor of 2.0 has been used for thermoplastic pipe.
The allowable constrained buckling pressure should be compared to the total vertical stress acting on the pipe crown from the combined load of soil, and ground water or floodwater. It is prudent to check buckling resistance against a ground water level for a 100-year-flood. In this calculation the total vertical stress is typically taken as the prism load pressure for saturated soil, plus the fluid pressure of any floodwater above the ground surface.

For DR pipes operating under a vacuum, it is customary to use Equation 3-15 to check the combined pressure from soil, ground water, and vacuum, and then to use the unconstrained buckling equation, Equation 3-39, to verify that the pipe can operate with the vacuum independent of any soil support or soil load, in case construction does not develop the full soil support. Where vacuum load is shortterm, such as during water hammer events two calculations with Equation 3-14 are necessary. First determine if the pipe is sufficient for the ground water and soil pressure using a long-term modulus; then determine if the pipe is sufficient for the combined ground water, soil pressure and vacuum loading using the short-term modulus.

## Constrained Buckling Example

Does a 36" SDR 26 PE4710 pipe have satisfactory resistance to constrained buckling when installed with 18 ft of cover in a compacted soil embedment? Assume ground water to the surface and an $\mathrm{E}^{\prime}$ of $1500 \mathrm{lb} / \mathrm{in}^{2}$.

SOLUTION: Solve Equation 3-15. Since this is a long-term loading condition, the 50 year stress relaxation modulus for PE4710 material is given in the Appendix to Chapter 3 as 29,000 psi. Soil cover, $H$, and ground water height, $\mathrm{H}_{\mathrm{GW}^{\prime}}$ are both 18 feet. Therefore, the soil support factor, $\mathrm{B}^{\prime}$, is found as follows;

$$
\mathrm{B}^{\prime}=-\frac{.65}{.}=.6
$$

## and the bouyancy reduction factor, $R$, is found as follows:

$R=.33-=.6$

Solve Equation 3-15 for the allowable long-term constrained buckling pressure:
$\mathrm{P}_{\mathrm{wc}}=\sqrt[5.65]{\frac{.6 \cdot 615}{12(26-1)^{3}}}$
$P_{\text {WC }}=23.5=3387$

The earth pressure and ground water pressure applied to the pipe is found using Equation 3-1 (prism load) with a saturated soil weight. The saturated soil weight being the net weight of both soil and water.

$$
P_{\mathrm{E}}=\quad=6-
$$

Fig. 7.16 Critical buckling pressure reduction factor C for shape.

According to Janson, when pipes are buried or installed in a way that allows soil or surrounding medium to provide some resistance against buckling or deflection, the buckling pressure $\left(\mathrm{P}_{\mathrm{b}}\right)$ in the soil is found to be:

## Equation 7.18

$$
\mathrm{P}_{\mathrm{b}}=1.15 \sqrt{\mathrm{P}_{\mathrm{cr}} \mathrm{E}^{\prime}}
$$

where:
$\mathrm{P}_{\mathrm{b}}=$ buckling pressure in a given soil, psi
$\mathrm{E}^{\prime}=$ modulus of soil reaction, psi

## Example 7.3

If a DR 35 PVC sewer pipe with a 400,000 psi modulus of elasticity is confined in a saturated soil providing $\mathrm{E}^{\prime}=800$ psi, what height $(\mathrm{H})$ of the saturated soil with density $120 \mathrm{lb} / \mathrm{ft}^{3}(\mathrm{w})$ would cause buckling? What maximum cover height ensures that deflection $\% \Delta \mathrm{Y} / \mathrm{D}$ does not exceed $7.5 \%$ ? Assume bedding angle of zero ( $\mathrm{K}=0.11$ ).

## Solution

Find first the critical buckling pressure, using Equation 7.14:

$$
\mathrm{P}_{\mathrm{cr}}=\frac{2 \mathrm{E}}{\left(1-\nu^{2}\right)(\mathrm{DR}-1)^{3}}=\frac{2(400,000)}{\left[1-(0.38)^{2}\right](35-1)^{3}}=23.8 \mathrm{psi}
$$

## Design of Buried PVC Pipe

Then, determine the buckling pressure in this soil:

$$
\mathrm{P}_{\mathrm{b}}=1.15 \sqrt{(23.8)(800)}=158.7 \mathrm{psi}=22,850 \mathrm{lb} / \mathrm{ft}^{2}
$$

This is, then, the prism load $\left(\mathrm{P}_{\mathrm{v}}\right)$, which is used to find maximum cover height H :

$$
\mathrm{H}=\mathrm{P}_{\mathrm{v}} / \mathrm{w}=22,850 / 120=190 \mathrm{ft}
$$

where:
$\mathrm{H}=$ height of fill above top of pipe, ft
$\mathrm{P}_{\mathrm{v}}=$ vertical soil pressure due to the prism load, $\mathrm{lb} / \mathrm{ft}^{2}$
To limit deflection $\% \Delta \mathrm{Y} / \mathrm{D}$ to $7.5 \%$, maximum cover height $(\mathrm{H})$ is found via prism load pressure (i.e., pressure of vertical column of soil) using Eq 7.9 with $\mathrm{W}^{\prime}=0$ :

$$
\begin{gathered}
\mathrm{w}=\text { Soil unit weight, } \mathrm{lb} / \mathrm{ft}^{3} \\
\% \Delta \mathrm{Y} / \mathrm{D}=\frac{\mathrm{KP}_{\mathrm{v}}(100)}{0.149 \mathrm{PS}+0.061 \mathrm{E}^{\prime}} \\
\mathrm{P}_{\mathrm{v}}=\frac{\% \Delta \mathrm{Y} / \mathrm{D}\left(0.149 \mathrm{PS}+0.061 \mathrm{E}^{\prime}\right)}{100 \mathrm{~K}}=\frac{7.5[(0.149)(46)+(0.61)(800)]}{(100)(0.11)} \\
=37.9 \mathrm{psi}=5,464 \mathrm{lb} / \mathrm{ft}^{2}
\end{gathered}
$$

Thus,

$$
\mathrm{H}(\text { to limit deflection })=5,464 / 120=45.5 \mathrm{ft}
$$

Maximum cover is limited by the allowable deflection, not by buckling. Therefore, the safety factor for the critical failure mode by buckling of DR 35 PVC pipe is ample.

### 7.8.7 Localized Profile Buckling Performance Limit

Localized profile buckling is known to be a design-limiting issue for some thermoplastic pipes. Evaluations of profile PVC pipe have shown that localized buckling is not a factor.

### 7.8.8 Wall-Crushing Performance Limit

Research has established that flexible steel pipe walls can buckle at deflections considerably less than $20 \%$ if load is large and the soil surrounding the pipe is extremely compacted. Based on these observations, H. L. White and J. P. Layer proposed the ring compression

## Deep Fill Installation

## Installation Category \#3: Deep Fill Installation

The performance limits for pipes in a deep fill are the same as for any buried pipe. They include:

1. Compressive ring thrust stress
2. Ring deflection
3. Constrained pipe wall buckling

The suggested calculation method for pipe in deep fill applications involves the introduction of design routines for each performance limit that are different than those previously given.

Compressive ring thrust is calculated using soil arching. The arching calculation may also be used for profile pipe designs in standard trench applications. Profile pipes are relatively low stiffness pipes where significant arching may occur at relatively shallow depths of cover.

At a depth of around 50 feet or so it becomes impractical to use Spangler's equation as published in this chapter because it neglects the significant load reduction due to arching and the inherent stiffening of the embedment and consequential increase in $\mathrm{E}^{\prime}$ due to the increased lateral earth pressure applied to the embedment. This section gives an alternate deflection equation for use with PE pipes. It was first introduced by Watkins et al. ${ }^{(1)}$ for metal pipes, but later Gaube extended its use to include PE pipes. ${ }^{(15)}$

Where deep fill applications are in dry soil, Luscher's equation (Eq. 3-15 or 3-16) may often be too conservative for design as it considers a radial driving force from ground water or vacuum. Moore and Selig ${ }^{(17)}$ developed a constrained pipe wall buckling equation suitable for pipes in dry soils, which is given in a following section.

Considerable care should be taken in the design of deeply buried pipes whose failure may cause slope failure in earthen structures, or refuse piles or whose failure may have severe environmental or economical impact. These cases normally justify the use of methods beyond those given in this Chapter, including finite element analysis and field testing, along with considerable professional design review.

## Compressive Ring Thrust and the Vertical Arching Factor

The combined horizontal and vertical earth load acting on a buried pipe creates a radially-directed compressive load acting around the pipe's circumference. When a PE pipe is subjected to ring compression, thrust stress develops around the pipe hoop, and the pipe's circumference will ever so slightly shorten. The shortening permits "thrust arching," that is, the pipe hoop thrust stiffness is less than the soil hoop thrust stiffness and, as the pipe deforms, less load follows the pipe. This occurs much like the vertical arching described by Marston. ${ }^{(18)}$ Viscoelasticity enhances this effect. McGrath ${ }^{(19)}$ has shown thrust arching to be the predominant form of arching with PE pipes.

Burns and Richard ${ }^{(6)}$ have published equations that give the resulting stress occurring in a pipe due to arching. As discussed above, the arching is usually considered when calculating the ring compressive stress in profile pipes. For deeply buried pipes McGrath ${ }^{(19)}$ has simplified the Burns and Richard's equations to derive a vertical arching factor as given by Equation 3-21.
(3-21)

$$
\mathrm{VAF}=0.88-0.71 \frac{\mathrm{~S}_{\mathrm{A}}-1}{\mathrm{~S}_{\mathrm{A}}+2.5}
$$

## WHERE

VAF = Vertical Arching Factor
$S_{A}=$ Hoop Thrust Stiffness Ratio
(3-22)

$$
\mathrm{S}_{\mathrm{A}}=\frac{1.43 \mathrm{M}_{\mathrm{S}} \mathrm{r}_{\mathrm{CENT}}}{\mathrm{EA}}
$$

## WHERE

$r_{\text {CENT }}=$ radius to centroidal axis of pipe, in
$M_{s}=$ one-dimensional modulus of soil, psi
$E=$ apparent modulus of elasticity of pipe material, psi (See Appendix, Chapter 3)
$A=$ profile wall average cross-sectional area, in²/in, or wall thickness (in) for DR pipe

One-dimensional modulus values for soil can be obtained from soil testing, geotechnical texts, or Table 3-12 which gives typical values. The typical values in Table 3-12 were obtained by converting values from McGrath ${ }^{(20)}$.

TABLE 3-12
Typical Values of $\mathrm{M}_{\mathrm{s}}$, One-Dimensional Modulus of Soil

| Vertical Soil Stress1 (psi) | Gravelly Sand/Gravels <br> 95\% Std. Proctor (psi) | Gravelly Sand/Gravels <br> $\mathbf{9 0 \%}$ Std. Proctor (psi) | Gravelly Sand/Gravels <br> $\mathbf{8 5 \%}$ Std. Proctor (psi) |
| :---: | :---: | :---: | :---: |
| 10 | 3000 | 1600 | 550 |
| 20 | 3500 | 1800 | 650 |
| 40 | 4200 | 2100 | 800 |
| 60 | 5000 | 2500 | 1000 |
| 80 | 6000 | 2900 | 1300 |
| 100 | 6500 | 3200 | 1450 |

* Adapted and extended from values given by McGrath ${ }^{(20)}$. For depths not shown in McGrath ${ }^{(20)}$, the MS values were approximated using the hyperbolic soil model with appropriate values for K and n where $\mathrm{n}=0.4$ and $K=200, K=100$, and $K=45$ for $95 \%$ Proctor, $90 \%$ Proctor, and $85 \%$ Proctor, respectively.
${ }^{1}$ Vertical Soil Stress $(\mathrm{psi})=[$ soil depth $(\mathrm{ft}) \times$ soil density $(\mathrm{pcf})] / 144$

The radial directed earth pressure can be found by multiplying the prism load (pressure) by the vertical arching factor as shown in Eq. 3-23.

## ${ }^{(3-23)} \mathrm{P}_{\mathrm{RD}}=(\mathrm{VAF}) \mathrm{wH}$

## WHERE

$P_{R D}=$ radial directed earth pressure, $\mathrm{lb} / \mathrm{ft}^{2}$
$w=$ unit weight of soil, pcf
$H=$ depth of cover, ft

The ring compressive stress in the pipe wall can be found by substituting $\mathrm{P}_{\mathrm{RD}}$ from Equation 3-23 for $\mathrm{P}_{\mathrm{E}}$ in Equation 3-13 for DR pipe and Equation 3-14 for profile wall pipe.

## Earth Pressure Example

Determine the earth pressure acting on a $36^{\prime \prime}$ profile wall pipe buried 30 feet deep. The following properties are for one unique $36^{\prime \prime}$ profile pipe made from PE3608 material. Other $36^{\prime \prime}$ profile pipe may have different properties. The pipe's crosssectional area, A , equals 0.470 inches $^{2} /$ inch, its radius to the centroidal axis is 18.00 inches plus 0.58 inches, and its apparent modulus is $27,000 \mathrm{psi}$. Its wall height is 2.02 in and its $\mathrm{D}_{\mathrm{O}}$ equals 36 in +2 ( 2.02 in ) or 40.04 in . Assume the pipe is installed in a clean granular soil compacted to $90 \%$ Standard Proctor (Ms = 1875 psi ), the insitu soil is as stiff as the embedment, and the backfill weighs 120 pcf. (Where the excavation
is in a stable trench, the stiffness of the insitu soil can generally be ignored in this calculation.) The following series of equations calculates the hoop compressive stress, S, in the pipe wall due to the earth pressure applied by the soil above the pipe. The earth pressure is reduced from the prism load by the vertical arching factor.
(From Equation 3-22)
$\mathrm{S}_{\mathrm{A}}=\frac{1.43\left(1875 \frac{\mathrm{lbs}}{\mathrm{inch}^{2}}\right)(18.58 \mathrm{inch})}{\left(28250 \frac{\mathrm{lbS}}{\mathrm{inch}^{2}}\right)\left(0.470 \frac{\mathrm{inch}^{2}}{\mathrm{inch}}\right)}=3.93$
(From Equation 3-21)
VAF $=0.88-0.71 \frac{3.75-1}{3.75+2.5}=0.56$
(From Equation 3-23)

$$
P_{\mathrm{RD}}=0.57(120 \mathrm{pcf})(30 \mathrm{ft})=2016 \frac{\mathrm{lb}}{\mathrm{ft}^{2}}
$$

(From Equation 3-14)
$\mathrm{S}=\frac{\mathrm{P}_{\mathrm{RD}} \mathrm{D}_{\mathrm{O}}}{288 \mathrm{~A}}=\frac{2052 \mathrm{psf}(40.04 \mathrm{in})}{288\left(0.470 \mathrm{in}^{2} / \mathrm{in}\right)}=596 \mathrm{psi} \leq 1000 \mathrm{psi}$
(Allowable compressive stress per Table C.1, Appendix to Chapter 3)

The secant modulus of the soil may be obtained from testing or from a geotechnical engineer's evaluation. In lieu of a precise determination, the soil modulus may be related to the one-dimensional modulus, $\mathrm{M}_{s^{\prime}}$ from Table 3-12 by the following equation where $\mu$ is the soil's Poisson ratio.
(3-26)

$$
E_{s}=M_{s} \frac{(1+\mu)(1-2 \mu)}{(1-\mu)}
$$

## TABLE 3-13

Typical range of Poisson's Ratio for Soil (Bowles ${ }^{(211)}$ )

| Soil Type | Poisson's Ratio, $\boldsymbol{\mu}$ |
| :--- | :--- |
| Saturated Clay | $0.4-0.5$ |
| Unsaturated Clay | $0.1-0.3$ |
| Sandy Clay | $0.2-0.3$ |
| Silt | $0.3-0.35$ |
| Sand (Dense) | $0.2-0.4$ |
| Coarse Sand (Void Ratio 0.4-0.7) | 0.15 |
| Fine-grained Sand (Void Ratio 0.4-0.7) | 0.25 |

Moore-Selig Equation for Constrained Buckling in Dry Ground
As discussed previously, a compressive thrust stress exists in buried pipe. When this thrust stress approaches a critical value, the pipe can experience a local instability or large deformation and collapse. In an earlier section of this chapter, Luscher's equation was given for constrained buckling under ground water. Moore and Selig ${ }^{(17)}$ have used an alternate approach called the continuum theory to develop design equations for contrained buckling due to soil pressure (buckling of embedded pipes). The particular version of their equations given below is more appropriate for dry applications than Luscher's equation. Where ground water is present, Luscher's equation should be used.

The Moore-Selig Equation for critical buckling pressure follows: (Critical buckling pressure is the pressure at which buckling will occur. A safety factor should be provided.)
(3-29)

$$
\mathrm{P}_{\mathrm{CR}}=\frac{2.4 \varphi \mathrm{R}_{\mathrm{H}}}{\mathrm{D}_{\mathrm{M}}}(\mathrm{El})^{\frac{1}{3}}\left(\mathrm{E}_{\mathrm{S}}^{*}\right)^{\frac{2}{3}}
$$

## WHERE

$P_{C R}=$ Critical constrained buckling pressure, psi
$\varphi=$ Calibration Factor, 0.55 for granular soils
$R_{H}=$ Geometry Factor
$E=$ Apparent modulus of elasticity of pipe material, psi
$I=$ Pipe wall moment of Inertia, in $4 /$ in ( $\mathbf{t}^{3} / 12$, if solid wall construction)
$E_{S}{ }^{*}=\mathrm{E}_{\mathrm{S}} /(1-\mu)$
$E_{S}=$ Secant modulus of the soil, psi
$\mu s=$ Poisson's Ratio of Soil (Consult a textbook on soil for values. Bowles (1982) gives typical values for sand and rock ranging from 0.1 to 0.4.)
The geometry factor is dependent on the depth of burial and the relative stiffness between the embedment soil and the insitu soil. Moore has shown that for deep burials in uniform fills, $\mathrm{R}_{\mathrm{H}}$ equals 1.0.

## Critical Buckling Example

Determine the critical buckling pressure and safety factor against buckling for the $6^{\prime \prime}$ SDR 11 pipe (5.987" mean diameter) in the previous example.

## SOLUTION:

$$
\begin{aligned}
& \mathrm{E}_{\mathrm{S}}^{*}=\frac{2000}{(1-0.3)}=2860 \frac{\mathrm{lbS}}{\mathrm{inch}^{2}} \\
& \mathrm{P}_{\mathrm{CR}}=\frac{2.4^{*} 0.55^{*} 1.0}{5.987}(2900 \sigma * 0.018)^{\frac{1}{3}}(2860)^{\frac{2}{3}}=358 \cdot \frac{\mathrm{lbS}}{\mathrm{in}^{2}}
\end{aligned}
$$

Determine the Safety Factor against buckling:

$$
\text { S.F. }=\frac{P_{C R}}{P_{E}}=\frac{358^{*} 144}{140 * 75}=4.9
$$

(1) Although there are various factors that determine the exact apparent modulus response of a PE, a major factor is its ratio of crystalline to amorphous content - a parameter that is reflected by a PE's density. Hence, the major headings PE2XXX, PE3XXX and, PE4XXX, which are based on PE's Standard Designation Code. The first numeral of this code denotes the PE's density category in accordance with ASTM D3350 (An explanation of this code is presented in Chapter 5).
(2) The values in this table are applicable to both the condition of sustained and constant loading (under which the resultant strain increases with increased duration of loading) and that of constant strain (under which an initially generated stress gradually relaxes with increased time).
(3) The design values in this table are based on results obtained under uni-axial loading, such as occurs in a test bar that is being subjected to a pulling load. When a PE is subjected to multi-axial stressing its strain response is inhibited, which results in a somewhat higher apparent modulus. For example, the apparent modulus of a PE pipe that is subjected to internal hydrostatic pressure - a condition that induces bi-axial stressing - is about $25 \%$ greater than that reported by this table. Thus, the Uni-axial condition represents a conservative estimate of the value that is achieved in most applications.

It should also be kept in mind that these values are for the condition of continually sustained loading. If there is an interruption or a decrease in the loading this, effectively, results in a somewhat larger modulus.
In addition, the values in this table apply to a stress intensity ranging up to about 400psi, a value that is seldom exceeded under normal service conditions.

Chapter 3 101
Material Properties
B. 2 - Approximate Values for the Condition of a Rapidly Increasing Stress OR Strain
B.2.1 - Values for the Base Temperature of $73^{\circ} \mathrm{F}\left(23^{\circ} \mathrm{C}\right)$

TABLE B.2.1

| "Dynamic" ${ }^{(3)}$ | 150,000psi (1,034MPa), For All Designation Codes |  |  |  |  |  |

(1) See Chapter 5 for an explanation of the PE Pipe Material Designation Code. The X's designate any numeral that is recognized under this code.
(2) Under ASTM D638, "Standard Test Method for Tensile Properties of Plastics", a dog-bone shaped specimen is subjected to a constant rate of pull. The "apparent modulus" under this method is the ratio of stress to strain that is achieved at a certain defined strain. This apparent modulus is of limited value for engineering design.
(3) The dynamic modulus is the ratio of stress to strain that occurs under instantaneous rate of increasing stress, such as can occur in a water-hammer reaction in a pipeline. This modulus is used as a parameter for the computing of a localized surge pressure that results from a water hammer event.

## B.2.2 - Values for Other Temperatures

The values for other temperatures may be determined by applying a multiplier, as follows, to the base temperature value:

- For Short-Term Apparent Modulus - Apply the multipliers in Table B.1.2
- For Dynamic Apparent Modulus - Apply the multipliers in Table B.2.2

TABLE B.2.2
Dynamic Modulus, Temperature Compensating Multipliers

| Temperature,${ }^{\circ} \mathbf{F}\left({ }^{\circ} \mathbf{C}\right)$ | Multiplier |
| :---: | :---: |
| $40(4)$ | 1.78 |
| $50(10)$ | 1.52 |
| $60(16)$ | 1.28 |
| $73.4(23)$ | 1.00 |
| $80(27)$ | 0.86 |
| $90(32)$ | 0.69 |
| $100(38)$ | 0.53 |
| $110(43)$ | 0.40 |
| $120(49)$ | 0.29 |

## WHERE

$P_{L}=$ vertical soil pressure due to surcharge pressure, $\mathrm{lb} / \mathrm{ft}^{2}$
$p_{a}=$ pressure due to sub-area $\mathbf{a}, \mathbf{l b} / \mathrm{ft}^{2}$
$p_{b}=\mathbf{p r e s s u r e}$ due to sub-area $\mathbf{b}, \mathbf{l b} / \mathbf{f t}^{2}$
$p_{c}=$ pressure due to sub-area $\mathbf{c}, \mathbf{l b} / \mathrm{ft}^{2}$
$p_{d}=\mathbf{p r e s s u r e}$ due to sub-area $\mathbf{d}, \mathbf{l b} / \mathbf{f t}^{2}$

## Pressure due to the surcharge applied to the i-th sub-area equals:

(3-7) $\rho_{1}=I_{V} W_{s}$

## WHERE

$I_{V}=$ Influence Value from Table 3-6
$w_{S}=$ distributed pressure of surcharge load at ground surface, $\mathrm{lb} / \mathrm{ft}^{2}$

If the four sub-areas are equivalent, then Equation 3-7 may be simplified to:
${ }^{(3-8)} P_{L}=4 I_{V} W_{S}$
The influence value is dependent upon the dimensions of the rectangular area and upon the depth to the pipe crown, H. Table 3-6 Influence Value terms depicted in Figure 3-6, are defined as:

```
= depth of cover, ft
= horizontal distance, normal to the pipe centerline, from the center of the load to the load edge, ft
= horizontal distance, parallel to the pipe centerline, from the center of the load to the load edge, ft
```

Interpolation may be used to find values not given in Table 3-6. The influence value gives the portion (or influence) of the load that reaches a given depth beneath the corner of the loaded area.

Figure 3-5 Illustration of Distributed Loads
and if half-full, the liquid weight is
(3-36)

$$
\mathrm{W}_{\mathrm{L}}=\omega_{\mathrm{L}} \frac{\pi \mathrm{~d}^{\prime 2}}{8}
$$

## WHERE

$\omega_{L}=$ unit weight of the liquid in the pipe, $\mathrm{lb} / \mathrm{ft}^{3}$
$d^{\prime}=$ pipe inside diameter, ft

For liquid levels between empty and half-full ( $0 \%$ to $50 \%$ ), or between half-full and full $(50 \%$ to $100 \%)$, the following formulas provide an approximate liquid weight with an accuracy of about $\pm 10 \%$. Please refer to Figure 3-8.

Figure 3-8 Flotation and Internal Liquid Levels

For a liquid level between empty and half-full, the weight of the liquid in the pipe is approximately
${ }^{(3-37)} W_{L}=\omega_{\llcorner } \frac{4 h_{1}^{3}}{3} \sqrt{\frac{d^{\prime}-h_{1}}{h_{1}}+0.392}$

## WHERE <br> $\mathrm{hl}=$ liquid level in pipe, ft

For a liquid level between half-full and full, the weight of the liquid in the pipe is approximately

$$
\mathrm{W}_{\mathrm{L}}=\omega_{\mathrm{L}}\left(\frac{\pi \mathrm{~d}^{\prime 2}}{4} \quad .3 \mathrm{~h}\right)
$$

Figure 3-9 Ovality Compensation Factor, $f_{\varnothing}$

The designer should compare the critical buckling pressure with the actual anticipated pressure, and apply a safety factor commensurate with their assessment of the application. A safety factor of 2.5 is common, but specific circumstances may warrant a higher or lower safety factor. For large-diameter submerged pipe, the anticipated pressure may be conservatively calculated by determining the height of water from the pipe invert rather than from the pipe crown.

## Ground Water Flotation Example

Find the allowable flood water level above a 10 " DR 26 PE4710 pipe installed with only 2 ft of cover. Assume the pipe has 3 percent ovality due to shipping, handling, and installation loads.

SOLUTION: Use Equation 3-39. The pipe wall buckling pressure depends upon the duration of the water level above the pipe. If the water level is long lasting, then a long-term value of the stress relaxation modulus should be used, but if the water level rises only occasionally, a shorter term elastic modulus may be applied.

Case (a): For the long lasting water above the pipe, the stress relaxation modulus at 50 year, $73^{\circ} \mathrm{F}$ is approximately $29,000 \mathrm{lb} / \mathrm{in}^{2}$ for a typical PE4710 material. Assuming $3 \%$ ovality (fo equals 0.76 ) and a 2.5 to 1 safety factor, the allowable long-term pressure, $\mathrm{P}_{\mathrm{WU}}$ is given by:
$P_{W U}=\frac{(0.76)}{2.5} \frac{2(2,000)}{\left(1-0.45^{2}\right)}\left(\frac{1}{26-1}\right)^{3}=1.4$ psi $\quad(3.2 \mathrm{ft}-\mathrm{d})$

## TABLE 3-8

Values of E' for Pipe Embedment (See Duncan and Hartley ${ }^{(10)}$ )

|  | $15-20$ | 1100 | 1700 | 2500 | 3800 |

## Soil Support Factor, Fs

Ring deflection and the accompanying horizontal diameter expansion create lateral earth pressure which is transmitted through the embedment soil and into the trench sidewall. This may cause the sidewall soil to compress. If the compression is significant, the embedment can move laterally, resulting in an increase in pipe deflection. Sidewall soil compression is of particular concern when the insitu soil is loose, soft, or highly compressible, such as marsh clay, peat, saturated organic soil, etc. The net effect of sidewall compressibility is a reduction in the soil-pipe system's stiffness. The reverse case may occur as well if the insitu soil is stiffer than the embedment soil; e.g. the insitu soil may enhance the embedment giving it more resistance to deflection. The Soil Support Factor, $\mathrm{F}_{S^{\prime}}$ is a factor that may be applied to $\mathrm{E}^{\prime}$ to correct for the difference in stiffness between the insitu and embedment soils. Where the insitu soil is less stiff than the embedment, $\mathrm{F}_{\mathrm{S}}$ is a reduction factor. Where it is stiffer, $\mathrm{F}_{\mathrm{S}}$ is an enhancement factor, i.e. greater than one.

The Soil Support Factor, FS, may be obtained from Tables 3-9 and 3-10 as follows:

- Determine the ratio $B_{d} / D_{O}$, where $B_{d}$ equals the trench width at the pipe springline (inches), and Do equals the pipe outside diameter (inches).
- Based on the native insitu soil properties, find the soil reaction modulus for the insitu soil, E'N in Table 3-9.
- Determine the ratio $\mathrm{E}^{\prime} \mathrm{N} / \mathrm{E}^{\prime}$.
- Enter Table 3-10 with the ratios $\mathrm{B}_{\mathrm{d}} / \mathrm{Do}_{0}$ and $\mathrm{E}^{\prime} \mathrm{N} / \mathrm{E}^{\prime}$ and find Fs.

TABLE 3-9
Values of E'N, Native Soil Modulus of Soil Reaction, Howard ${ }^{(3)}$

## Lag Factor and Long-Term Deflection

Spangler observed an increase in ring deflection with time. Settlement of the backfill and consolidation of the embedment under the lateral pressure from the pipe continue to occur after initial installation. To account for this, he recommended applying a lag factor to the Iowa Formula in the range of from 1.25 to 1.5. Lag occurs in installations of both plastic and metal pipes. Howard ${ }^{(3,11)}$ has shown that the lag factor varies with the type of embedment and the degree of compaction. Many plastic pipe designers use a Lag Factor of 1.0 when using the prism load as it

## Appendix C

## Allowable Compressive Stress

Table C. 1 lists allowable compressive stress values for $73^{\circ} \mathrm{F}\left(23^{\circ} \mathrm{C}\right)$. Values for allowable compressive stress for other temperatures may be determined by application of the same multipliers that are used for pipe pressure rating (See Table A.2).

## TABLE C. 1

Allowable Compressive Stress for $73^{\circ} \mathrm{F}\left(23^{\circ} \mathrm{C}\right)$

(1) See Chapter 5 for an explanation of the PE Pipe Material Designation Code.

## Appendix D <br> Poisson's Ratio

Poisson's Ratio for ambient temperature for all PE pipe materials is approximately 0.45 .

This 0.45 value applies both to the condition of tension and compression. While this value increases with temperature, and vice versa, the effect is relatively small over the range of typical working temperatures.

Figure 3-3 AASHTO H2O and HS2O Vehicle Loads

## Impact Factor

Road surfaces are rarely smooth or perfectly even. When vehicles strike bumps in the road, the impact causes an instantaneous increase in wheel loading. Impact load may be found by multiplying the static wheel load by an impact factor. The factor varies with depth. Table 3-2 gives impact factors for vehicles on paved roads. For unpaved roads, impact factors of 2.0 or higher may occur, depending on the road surface.

TABLE 3-2
Typical Impact Factors for Paved Roads

| Cover Depth, $\mathbf{f t}$ | Impact Factor, $\mathbf{I}_{\mathbf{f}}$ |
| :---: | :---: |
| 1 | 1.35 |
| 2 | 1.30 |
| 3 | 1.25 |
| 4 | 1.20 |
| 6 | 1.10 |
| 8 | 1.00 |

Derived from Illinois DOT dynamic load formula (1996).

Vehicle Loading through Highway Pavement (Rigid)
Pavement reduces the live load pressure reaching a pipe. A stiff, rigid pavement spreads load out over a large subgrade area thus significantly reducing the vertical

## IPS Size and Dimension Data

## DriscoPlex ${ }^{\circledR}$ Municipal \& Industrial \& Energy Series/IPS Pipe Data

Pressure Ratings are calculated using 0.63 design factor for HDS at $73^{\circ} \mathrm{F}$ as listed in PPI TR-4 for PE 4710 materials.
Temperature, Chemical, and Environmental use considerations may require use of additional design factors.

Pipe weights are calculated in accordance with PPI TR-7. Average inside diameter is calculated using nomnal OD and Minimum wall plus $6 \%$ for use in estimating fluid flows. Actual ID will vary. When designing components to fit the pipe ID, refer to pipe dimension and tolerances in the applicable pipe manufacturing specification.

## IPS Size and Dimension Data

PE4710 (PE3408)
DriscoPlex ${ }^{\circledR}$ Municipal \& Industrial \& Energy Series/IPS Pipe Data
Pressure Ratings are calculated using 0.63 design factor for HDS at $73^{\circ} \mathrm{F}$ as listed in PPI TR-4 for PE 4710 materials.
Temperature, Chemical, and Environmental use considerations may require use of additional design factors.
