

## Distance Luminosity Exercises Solutions

Ex.3:

Determine the Apparent Magnitude of the red dwarf Proxima Centauri from a distance of 1AU.

In other words, how bright would it be if we replaced the Sun with Proxima Centauri?

Absolute Magnitude (M) Proxima Centauri: + **15.53**

|  |   |
|--|---|
| Formula:<br>$m - M = 5 \log d - 5$<br>change to:<br>$m = 5 \log d - 5 + M$ | $d = 1 \text{ AU (change to pc)}$<br>$1 \text{ pc} \sim 2.06 \times 10^5 \text{ AU}$<br>$1 \text{ AU} = \frac{1}{2.06 \times 10^5} = 4.854 \times 10^{-6} \text{ pc}$<br>$1 \text{ AU} \sim .000005 \text{ pc}$ |
|--|---|

$$m = 5 \log d - 5 + M$$

$$m = 5 \log .000005 - 5 + 15.53$$

$$m = 5 \log .000005 - 5 + 15.53$$

$$m = 5 (-5.301) - 5 + 15.53$$

$$m = -26.505 - 5 + 15.53$$

$$= \boxed{-15.975}$$

- So that's a fair bit brighter than the full moon

( $m = -13$ ),

but nowhere near as bright as the Sun

( $m = -27$ )

Ex. 4:

Astronomers discover a Type IA supernova in a galaxy cluster with an Apparent Magnitude of + 15.819. Determine the distance to the Galaxy cluster. **Express your final answer in Light Years.**

**Working Formula:**

$$d = 10^{(m - M + 5)/5} \quad (\text{"d" is in parsecs})$$

**Data:**

$$m = +15.819 \text{ (given)}$$

$$M = -19 \text{ (absolute magnitude of a Type Ia Supernova)}$$

$$d = 10^{(15.819 - (-19) + 5)/5}$$

$$d = 10^{(39.819)/5}$$

$$d = 10^{7.9638}$$

$$= 92,002,578.66 \text{ pc}$$

$$\times 3.26$$

$$(1 \text{ pc} = 3.26 \text{ LY})$$

$$= 299,928,406.4 \text{ LY}$$
